

# Pseudorandom generator (PRG)

# Pseudorandom Generator (PRG)

- Given a seed, it outputs a sequence of random bits

$\text{PRG}(\text{seed}) \rightarrow \text{random bits}$

- It can output arbitrarily many random bits

# PRG security

- Can  $\text{PRG}(K)$  be truly random?

No. Consider key length  $|K|=k$ . Have  $2^k$  possible initial states of PRG. Deterministic from then on. There are more random states.

- A secure PRG suffices to “look” random (“pseudo”) to an attacker (no attacker can distinguish it from a random sequence)

# Example of PRG: using block cipher in CTR mode

If you want  $m$  random bits, and a block cipher with  $E_k$  has  $n$  bits, apply the block cipher  $m/n$  times and concatenate the result:

$$\text{PRG}(K \mid IV) = E_k(IV \mid 1) \mid E_k(IV \mid 2) \mid E_k(IV \mid 3) \dots E_k(IV \mid \text{ceil}(m/n)), \quad \text{where } \mid \text{ is concatenation}$$

# Application of PRG: Stream ciphers

- Another way to construct encryption schemes
- Similar in spirit to one-time pad: it XORs the plaintext with some random bits
- But random bits are not the key (as in one-time pad) but are output of a pseudorandom generator PRG

# Application of PRG: Stream cipher

Enc(K, M):

- Choose a random value IV
- $C = \text{PRG}(K \parallel \text{IV}) \text{ XOR } M$
- Output (IV, C)

Q: How decrypt?

A: Compute  $\text{PRG}(K \parallel \text{IV})$  and XOR with ciphertext C

Q: What is advantage over OTP?

A: Can encrypt any message length because PRG can produce any number of random bits, and multiple times because IV is chosen at random in Enc

# Discrete Logarithm Problem (DLP)

$$f(x) = \underbrace{g^x}_{y} \bmod p \text{ where } p \text{ is a large prime (2048 bits long)}$$

$g$  is a random value in  $[2, p-1]$

Assumption:  $f_{\text{DLP}}$  is OWF

Easy to compute:

Say  $x$  is 2048-bit large number.  
 $\approx 2^{2048}$   $2^{128}$

repeated squaring

$$\begin{array}{c} 2^{32} \\ \swarrow \quad \searrow \\ 2^{16} \quad 2^{16} \\ \swarrow \quad \searrow \\ 1 \text{ mult} \\ 2^{16} \cdot 2 \cdot 2 \cdot 2 \cdot \dots \\ \hline 16 \end{array}$$

# Diffie-Hellman Key Exchange (1976)

(Turing award)

large prime  $p$ ,  $1 < g < p-1$   
public

Alice

$$a \xleftarrow{R} \{1, \dots, p-2\}$$

secret

$$A = g^a \text{ mod } p$$

public

$$B^a = g^{ab} \text{ mod } p$$

$\parallel$   
K

Bob

$$b \xleftarrow{R} \{1, \dots, p-2\}$$

secret

$$B = g^b \text{ mod } p$$

public

$$A^b = g^{ab} \text{ mod } p$$

$\parallel$   
K

Symmetric-Key  
encryption communication  
using K

Eve sees:  $A = g^a \text{ mod } p \Rightarrow$  cannot compute  $a$   
 $B = g^b \text{ mod } p \Rightarrow$  cannot compute  $b$  } cannot compute  $g^{ab}$

Assumption: you cannot break DLP (DLP is OWF)  $\leftarrow$  necessary  
 Adv you cannot compute  $g^{ab} \text{ mod } p$  from  $g^a, g^b \text{ mod } p$
